The forward fast power control can control the transmit power of forward channel accurately, reducing interference and improving the capacity.

ii. Reverse power control

Reverse power control includes open-loop power control and close-loop power control. The close-loop power control can be further classified into inner-loop power control and outer-loop power control.

- Open-loop power control
The MS determines the transmit power to access the BTS according to the received pilot signal strength.
- Close-loop power control
The BTS issues a power control command to the MS, and performs the adjustment according to the feedback from the MS.

Figure 4-1 illustrates the principle of close-loop power control.

Figure 4-1 Close-loop power control

In the inner-loop power control mode, the BTS issues the power control bit according to the received Eb/Nt value.

In the outer-loop power control mode, the BSC adjusts the Eb/Nt setting value according to the Frame Error Rate (FER) of the received reverse signal. Then the BTS uses the newly set Eb/Nt value to issue the power control bit. In this way, the transmit power of the MS can be controlled.
